What is Purple Loosestrife?
Purple loosestrife is a wetland plant native to Europe and Asia where native insects and diseases have kept it in check. Introduced to North America in the 1800s as a garden plant, purple loosestrife has since spread to wild areas and degraded habitat for native plants and animals.

How to Identify Purple Loosestrife

**Fruit and Seeds:** Seed pod, small, abundant seed production.

**Flowers:** Numerous, purple clusters of two to several, 5-7 petals; blooms July through September.

**Leaves:** Pointed or linear shape; opposite or spiraled around stem; flat to somewhat curved; 1-4”; larger leaves at the base.

**Stems:** Squarish, 4-6 sided, smooth or fine-haired with leaves equally spaced along the stem. Becomes woody as plant matures.
Assess the Situation

Is purple loosestrife present at this site?

Yes

Is the population small/new?

Yes

Undertake control as soon as appropriate.
Focus on sites with important features (e.g. rare species and communities) first.
Monitor efficacy of control measures.
Evaluate if site restoration is required or if site will regenerate on its own.

No

Monitor site regularly to ensure early detection of new populations.

Population is large or well-established.
Recognize control may take time and resources.

Are there important features present at site?
These could include:
• Rare species or communities
• Resources (e.g. forestry)
• Recreation/aesthetic amenities

Yes

Prevent spread, focusing on dispersal pathways such as waterways.
If resources allow, remove satellite populations and work on edges reversing the invasion front.

No

Focus on protecting important features with control efforts in these areas.
Remove smaller populations and work on edges first, reversing the invasion front.
Monitor efficacy of control measures.
Evaluate if site restoration is required or if site will regenerate on its own.

Develop a long-term plan
Planning ahead allows you to evaluate the success of your efforts. Follow these steps to make the most of your management efforts.

1. **Focus** your efforts on preventing spread by controlling isolated plants and small populations outside the primary infestation site.

2. **Concentrate** on high-priority areas (most productive or sensitive part of an ecosystem, such as high-quality wetlands and undeveloped lakeshores).

3. **Dedicate** a certain time of each year to control efforts, and coordinate with your neighbors and other groups to set and meet your management goals.

4. **Replant** native plants once purple loosestrife infestation is reduced or eradicated. Minimizing the area of bare soil will help prevent any other invasive species from taking over.

5. **Follow Up** by removing seedlings that may sprout after initial control efforts.

### Choose the Best Control Method

Choosing the best control method when managing for purple loosestrife is extremely important. Inappropriate methods can cause plants to grow more and spread easier. There are three broad categories in which invasive plants are controlled: mechanical, chemical, and biological.

<table>
<thead>
<tr>
<th>Type of Control</th>
<th>What is it?</th>
<th>How to</th>
<th>Permit</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Mechanical</strong></td>
<td>Mechanical control is the physical removal of plants from the environment through cutting and digging.</td>
<td>Cutting the flower heads is the easier method, but digging is more effective. Be careful, as roots will grow more if left behind after digging. Cut the flower heads in late June to early August, before the plant goes to seed. Cut 1/3 of the top of the plant, so it does not sprout at the base. Dispose of cut purple loosestrife in black plastic trash bag. Seal the bag tightly and leave it in direct sunlight for 1-3 weeks—this kills any living plant material. Check the bag to ensure all plant material has died and then deposit in a landfill.</td>
<td>No permit is needed</td>
</tr>
<tr>
<td><strong>Biological</strong></td>
<td>Biological control uses natural predators specific to an invasive species. This method does not kill all plants, but rather renders populations manageable and keeps them from spreading.</td>
<td>The Galerucella beetle is typically released in Northern Michigan to eat the plants. Beetles should be released in the spring before plants flower, however, noting your purple loosestrife population’s location, size, and density when it is still flowering the previous fall will help determine how many beetles are necessary. Beetles can be moved within the State of Michigan without a permit. If you need additional beetles, contact the Watershed Council for ordering details at the beginning of each calendar year.</td>
<td></td>
</tr>
<tr>
<td><strong>Chemical</strong></td>
<td>Application of herbicide typically kills plants.</td>
<td>Use The Nature Conservancy’s “Bloody Glove Technique,” to wipe the herbicide on the top third of individual plants. <a href="https://www.invasive.org/gist/moredocs/lytsa01.pdf">https://www.invasive.org/gist/moredocs/lytsa01.pdf</a></td>
<td>A Michigan Department of Environmental Quality Aquatic Nuisance Permit is required for use of chemicals in waters of the State.</td>
</tr>
</tbody>
</table>
Suggested purple loosestrife control measures according to infestation size and infested area density.

### Size of Area to be Managed

<table>
<thead>
<tr>
<th>Percent of Area Covered with Purple Loosestrife</th>
<th>Isolated Plants</th>
<th>Small Infestation &lt;0.5 hectare / 1 acre</th>
<th>Medium &lt;0.5 - 2 hectares / 1-4 acres</th>
<th>Large &gt; 2 hectares / 4 acres</th>
</tr>
</thead>

### Make Your Efforts Known

Report any invasive species (plant or animal) to the Midwest Invasive Species Information Network online at [https://www.misin.msu.edu/](https://www.misin.msu.edu/) or through their smartphone app (MISIN). You can also use your local Cooperative Invasive Species Management Area coordinator as a resource for help with costs, advice, and reporting invasive species.
